

**Definition** A walk  $W = v_0v_1\dots v_n$  in a graph  $G$  is called *closed* if  $v_0 = v_n$ .

Note that if  $w$  is a closed walk then for each  $i$ :  $v_iv_{i+1}\dots v_nv_1\dots v_{i-1}v_i$  is also a closed walk.

**Definition** An *Eulerian circuit* (or Euler tour) in a graph  $G$  is a closed walk that contains every edge of  $G$  exactly once.

**Definition** A graph  $G$  is called *even* if all its vertices have even degree.

**Important Note** If  $v$  is a vertex in  $G$ , then any closed walk  $w$  contains an even number of the edges incident to  $v$  (half going in, half going out).

Thus, if  $G$  has an Eulerian circuit, it must be even.

**Theorem** Let  $G$  be a connected graph. Then  $G$  has an Eulerian circuit if and only if it is even.

---

**Proof** ( $\implies$ ) we just covered.

**Proof** ( $\impliedby$ ) Let  $G$  be an even connected graph. We use induction on  $m = |E(G)|$

For  $m = 0$  then  $G$  has one vertex  $v_0$  which is a trivial Eulerian circuit.

**Inductive Hypothesis** Assume  $m \geq 1$  and that every even connected graph with fewer than  $m$  edges has an Eulerian circuit.

Consider  $G$  with  $m$  edges. Since  $G$  is connected and has some edges, every vertex has degree  $\geq 2$ . Then by earlier lemma, if every vertex in a graph has a degree at least two then  $G$  must have a cycle (by earlier lemma).

If  $C = v_1 \dots v_k$  then note that  $v_1 v_2 \dots v_k v_1$  is a closed walk.

Let  $G' = G - E(C)$  be the graph obtained from  $G$  by removing the edges of  $C$ .

Since  $G$  is even, every vertex has even degree. The degree of each  $v \in V(G')$  is

- $\deg_G(v)$  if  $v \notin V(C)$
- $\deg_G(v) - 2$  if  $v \in V(C)$

Therefore  $G'$  is an even graph. We can't yet say that  $G'$  is connected... But we can say that every component of  $G'$  is a connected even graph with  $< m$  edges.

Hence by **IH** each component  $G_i$  of  $G'$  has an Eulerian circuit  $W_i$ .

Since  $G$  is connected, each  $G_i$  contains a vertex  $a_i$  of  $C$ .

View each  $W_i$  as starting and ending of  $a_i$ . (See Figure 1).

Then by taking the closed walk around  $C$  and inserting at each  $a_i$  the Eulerian circuit  $w_i$  of  $G_i$ , we obtain an Eulerian circuit of  $G$ .

Hence by induction the theorem is proved  $\square$ .

Figure 1: Visualization of Eulerian Proof Concept

**Definition** A *bridge* in a graph  $G$  is an edge  $w$  with the property that  $G - e$  (the graph with vertex set  $V(G)$  and the edge set  $E(G) - \{e\}$ ) has more components than  $G$ .

In particular if  $G$  is connected then a bridge is an edge  $e$  such that  $G - e$  is disconnected.
