

### ***Matchings Recap***

A matching  $M$  saturates the vertices that are in the matching. A matching of maximum size is a *maximum matching* and a matching where every vertex is saturated by it is a *perfect matching*.

Note: a graph needs to have an even number of vertices for a perfect matching to exist.

**Definition** Let  $M$  be a matching in  $G$ . An *alternating path* with respect to  $M$  is a path in  $G$  which has every second edge in  $M$

**Definition** An *augmenting path* is an alternating path that begins and ends with an edge not in  $M$ .

Note that switching along an augmenting path makes the matching larger. For augmenting path  $P$  and matching  $M$ , “switching” means  $\{E(M) \setminus \{E(M) \cap E(P)\}\} \cup \{E(P) \setminus E(M)\}$ .

If our augmenting path starts and ends at unsaturated vertices, this switching produces a new, larger matching.

Note that augmenting paths always have odd length.

**Theorem** Let  $G$  be a graph and  $M$  a matching in  $G$ . If  $G$  has an augmenting path with respect to  $M$ , then  $M$  is not a maximum matching.

**Proof** Suppose  $G$  has an augmenting path  $P$ . Then  $P$  contains more edges not in  $M$  than in  $M$ .

Let  $M'$  be the set removing the edges in  $E(M) \cap E(P)$  from  $M$  and adding the edges of  $E(P) \setminus E(M)$  to  $M$ .

Since the endpoints of  $P$  are unsaturated, no vertex in  $V(M')$  is incident to more than one edge in  $M'$ . Hence  $M'$  is a matching

Since  $|E(P) \setminus E(M)| > |E(M) \cap E(P)|$ ,  $|M'| > |M|$ . Thus  $M$  is not a maximum matching  $\square$

**Definition** A *cover* in a graph  $G$  is a set of vertices  $C$  such that every edge in  $G$  is incident to at least one vertex in  $C$ .

A cover in a bipartite graph is either the characteristic set  $A$  or  $B$ .

**Lemma** Let  $G$  be a graph,  $M$  a matching and  $C$  a cover. Then

$$|M| \leq |C|$$

**Proof** Every edge in  $M$  is incident to at least one vertex in  $C$ .

Also, no two edges are incident to the same vertex in  $C$ . Thus  $|M| \leq |C|$ ,  $\square$ .

**Lemma** Let  $G$  be a graph,  $M$  a matching, and  $C$  a cover. If  $|M| = |C|$  then  $M$  is a maximum matching and  $C$  is a minimum cover.

**Proof** Let  $M'$  be a maximum matching. Then  $|M'| \leq |C|$  by previous lemma. As  $|C| = |M|$ ,  $|M'| \leq |C| = |M|$ , so  $M$  is a maximum matching.

Let  $C'$  be a minimum cover. Then  $|C'| \geq |M|$  by previous lemma. Since  $|M| = |C|$ ,  $|C'| \geq |M| = |C|$ , so  $C$  is a minimum cover.  $\square$ .

However, not there are graphs with  $|C| > |M|$  - more common when a perfect matching doesn't exist.

### Setting up definitions for next class

For a bipartite graph  $(A, B)$ .

Let  $X_0 = \{v \in A : v \text{ is not saturated by } M\}$ .

Let  $X = \{v \in A : \text{there is an alternating path from } v \text{ to a vertex in } X_0\}$

Let  $Y = \{v \in B : \text{there is an alternating path from } v \text{ to a vertex in } X_0\}$
